APS March Meeting 2014

# Why Characterize Quantum Operations?

- Better understanding of the errors in system
  - If know cause of errors, easier to correct
  - Can determine if error rates are low enough to apply error correcting codes / if codes will counteract the errors

# Standard Techniques Not Robust

Need perfect knowledge of state preparation, measurement and other operations. Otherwise give inaccurate or even invalid results.

**Not “robust”**

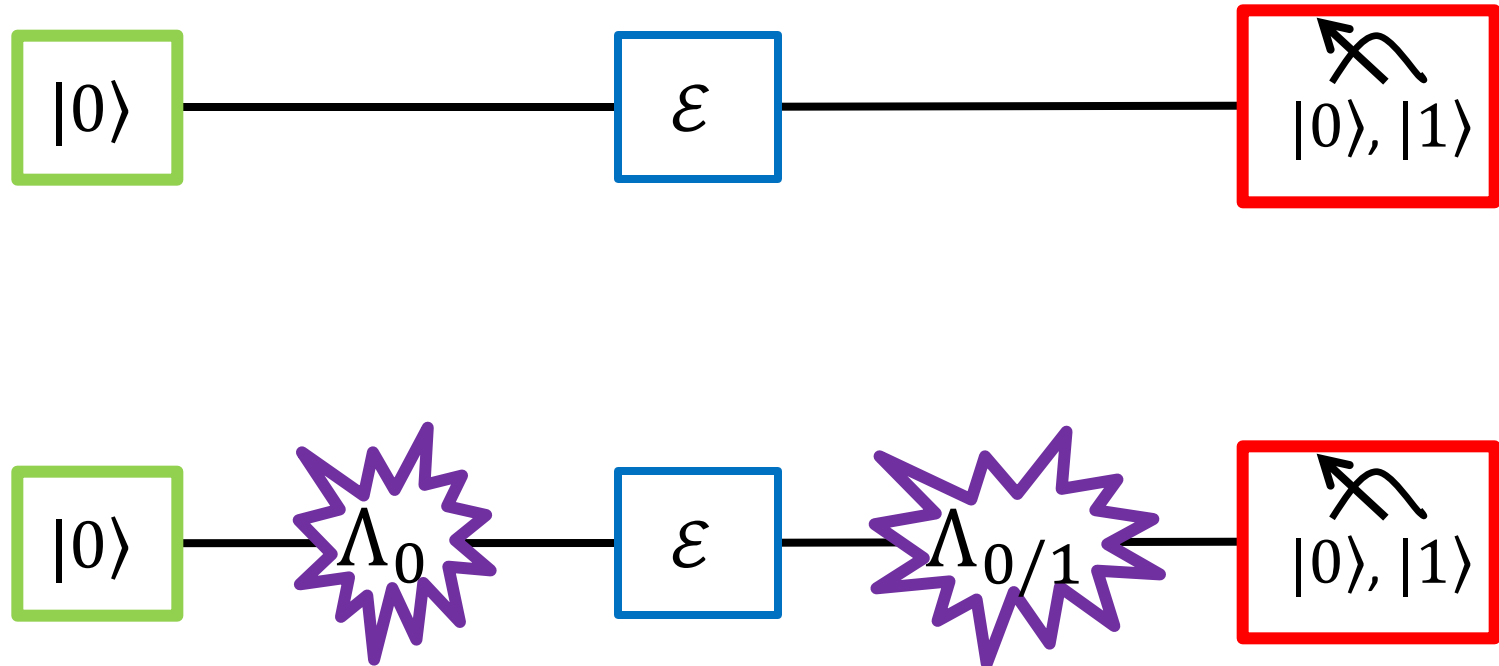

# Robust Techniques

- Gate Set Tomography Procedures [Stark '13, Blume-Kohout et al. '13, Merkel et al. '12]
  - Characterizes many processes at once
- Randomized Benchmarking (RB) [Emerson et al. '05, Knill et al. '08, Magesan et al. '11, '12]
  - Can only characterize ~~1~~ parameter of ~~1~~ type of process.  
almost all any
  - Can efficiently test performance of a universal gate set.

# Outline

- **Background:**
  - Standard Process Tomography
  - Randomized benchmarking framework, challenges of current implementation
- **Our Results:**
  - Robust characterization of unital part of any process
  - Experimental results and challenges

# Problem with Standard Process Tomography

# Problem with Standard Process Tomography

# Problem with Standard Process Tomography

$\neq$

# Randomized Benchmarking (RB)

Randomizing Clifford Unitaries

Recovery chosen so if  $\varepsilon = \mathbb{I}$ , whole sequence becomes identity.

# Randomized Benchmarking

- State Prep and Measurement don't affect decay parameter
- If Cliffords are perfect, recovery Clifford chosen so that if  $\mathcal{E}$  is identity, whole sequence is identity, then decay constant depends only on average fidelity of  $\mathcal{E}$  to identity

# Randomized Benchmarking

Randomizing Cliffords  
Have Errors!

Recovery Unitaries

# Randomized Benchmarking

## Pros

1. State preparation and measurement completely factored out
2. Easy to fit exponential decays

## Issues

1. How can we extract more than just 1 parameter?
2. How can we deal with errors on the randomizing operations?

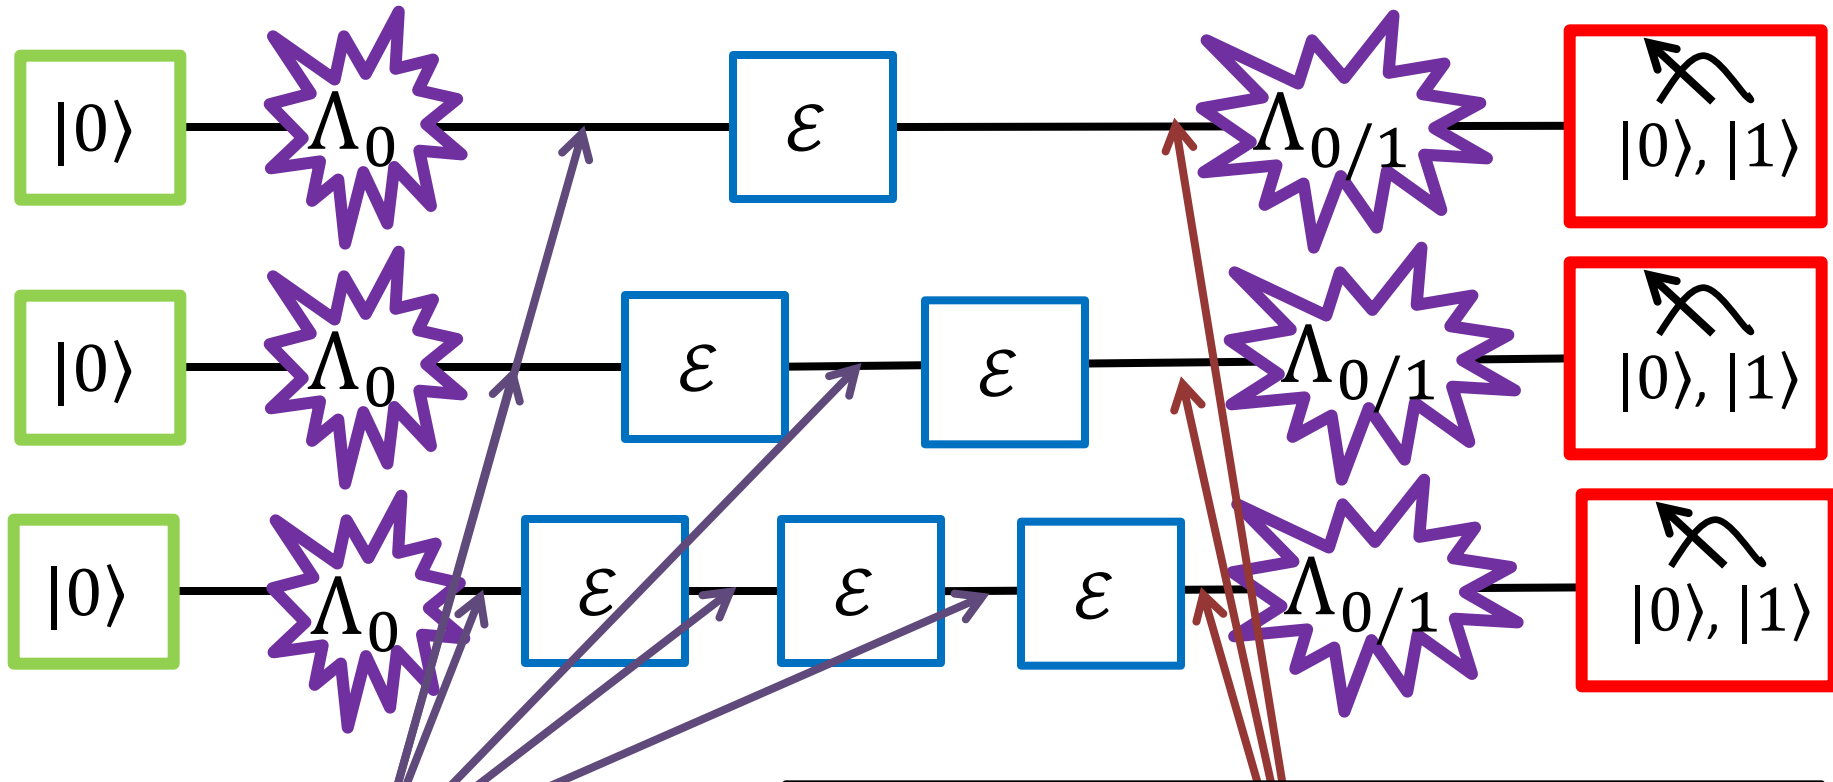

# 1. Extracting More Information

Randomizing Cliffords

Recovery chosen so if  $\epsilon = \mathbb{I}$ , whole sequence becomes identity.

# 1. Extracting More Information

Randomizing  
Cliffords

Recovery chosen so if  $\epsilon = C_x$ ,  
 $C_x$  a Clifford, whole sequence  
becomes identity.

# 1. Extracting More Information

Decay constant depends on 1 parameter of  $\mathcal{E}$ :

***Average Fidelity of  $\mathcal{E}$  to  $C_x$***  (can have fast decays)

# 1. Extracting More Information

Quantum map:  $16^n - 4^n$  parameters for  $n$ -qubit map

To compose two maps, just multiply matrices!

$$4^n \begin{bmatrix} 1 & 0 & \dots & 0 \\ \hline & \text{shaded} & & \end{bmatrix}$$

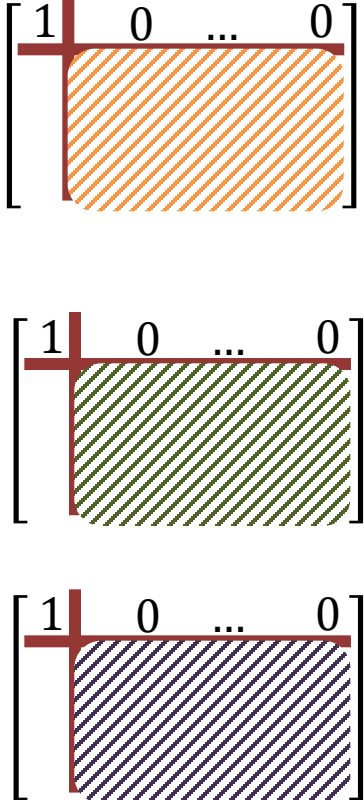

- Vectors  $V$  span a subspace  $S$
- Learn inner product between  $V$  and unknown vector  $u$
- Can learn projection of  $u$  onto  $S$
- Cliffords span unital part
- Learn inner product between Cliffords and  $\mathcal{E}$
- Learn projection of  $\mathcal{E}$  onto unital subspace

## 2. Dealing with Errors

## 2. Dealing with Errors

$$\begin{array}{l} \text{almost complete characterization of } \Lambda_C \\ + \\ \text{almost complete characterization of } \Lambda_C \circ \mathcal{E} \\ = \\ \text{almost complete characterization of } \mathcal{E} \end{array}$$

Without many of the systematic errors of previous procedures!

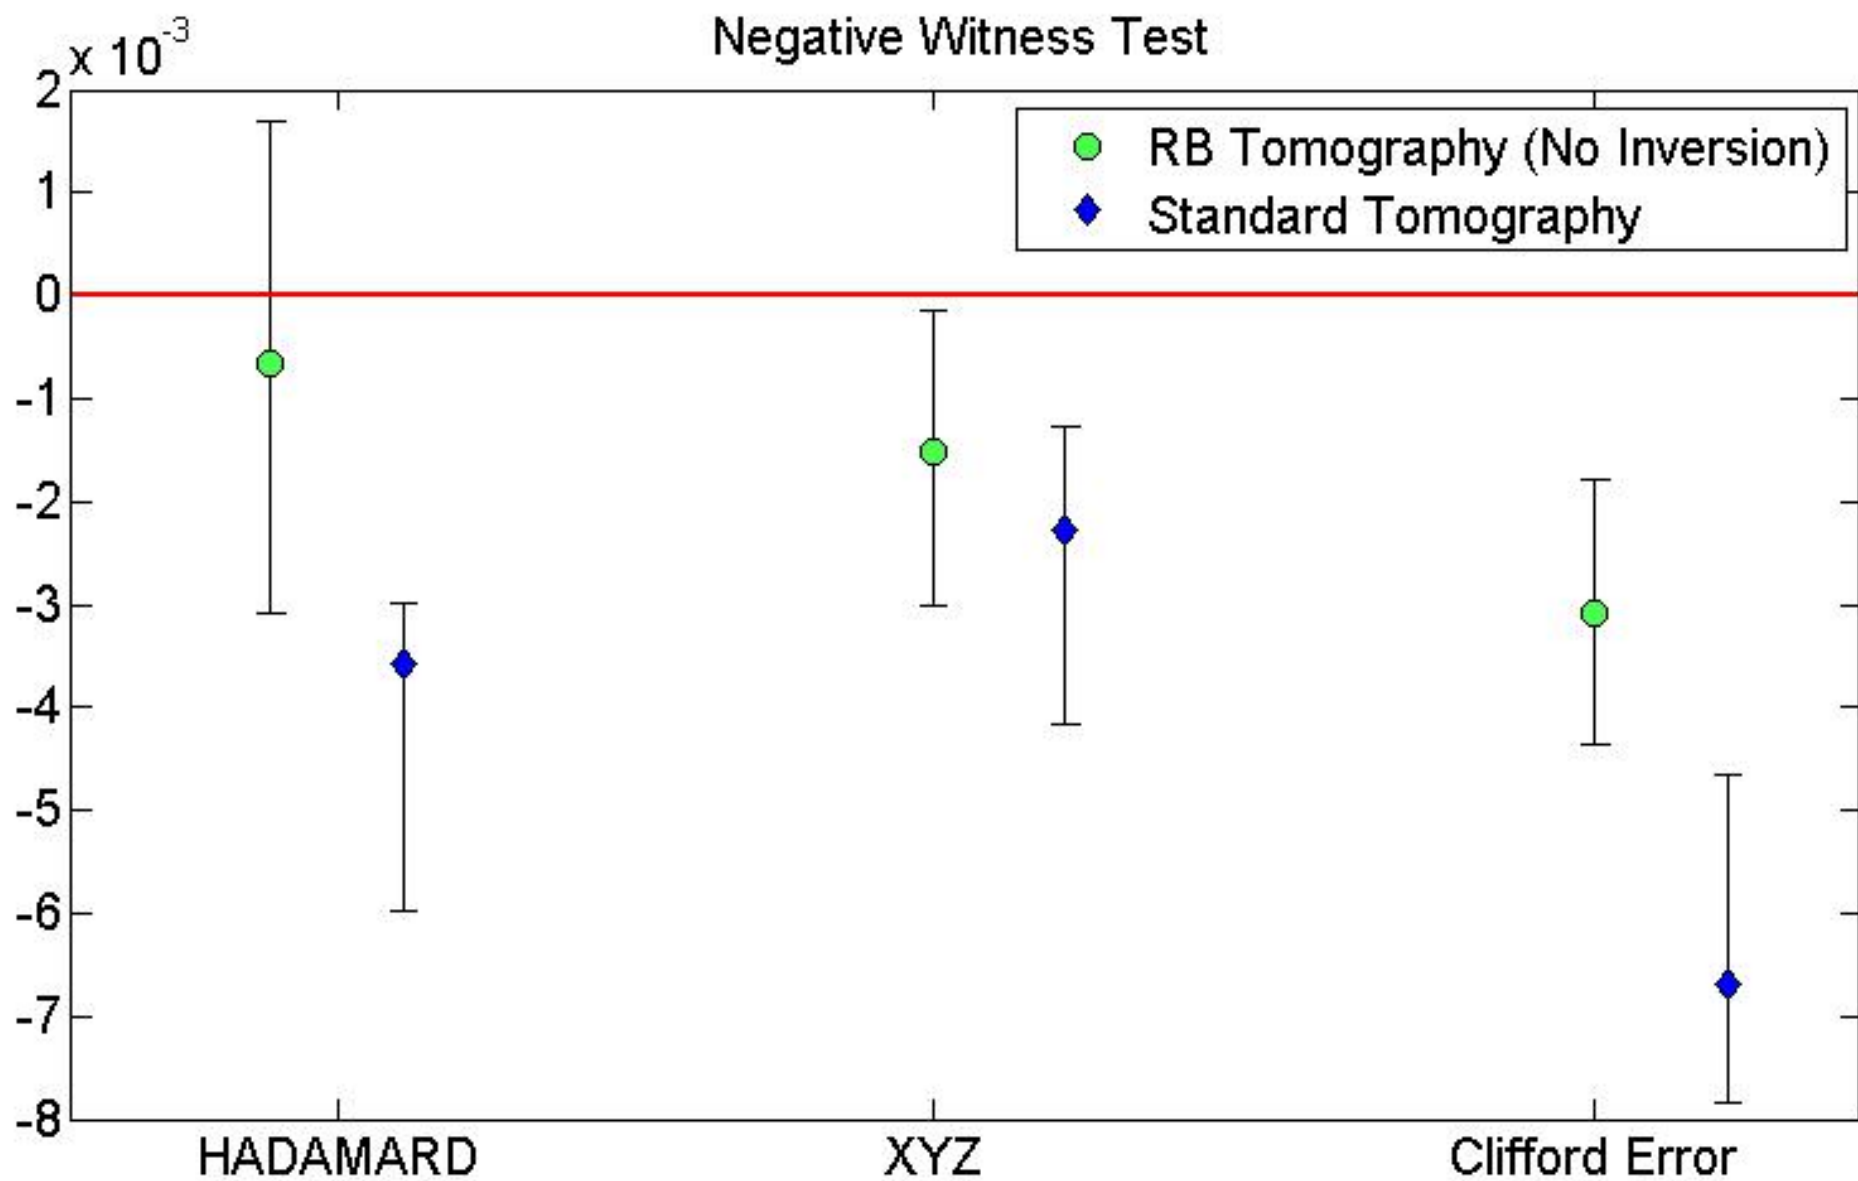

# Experimental Implementation

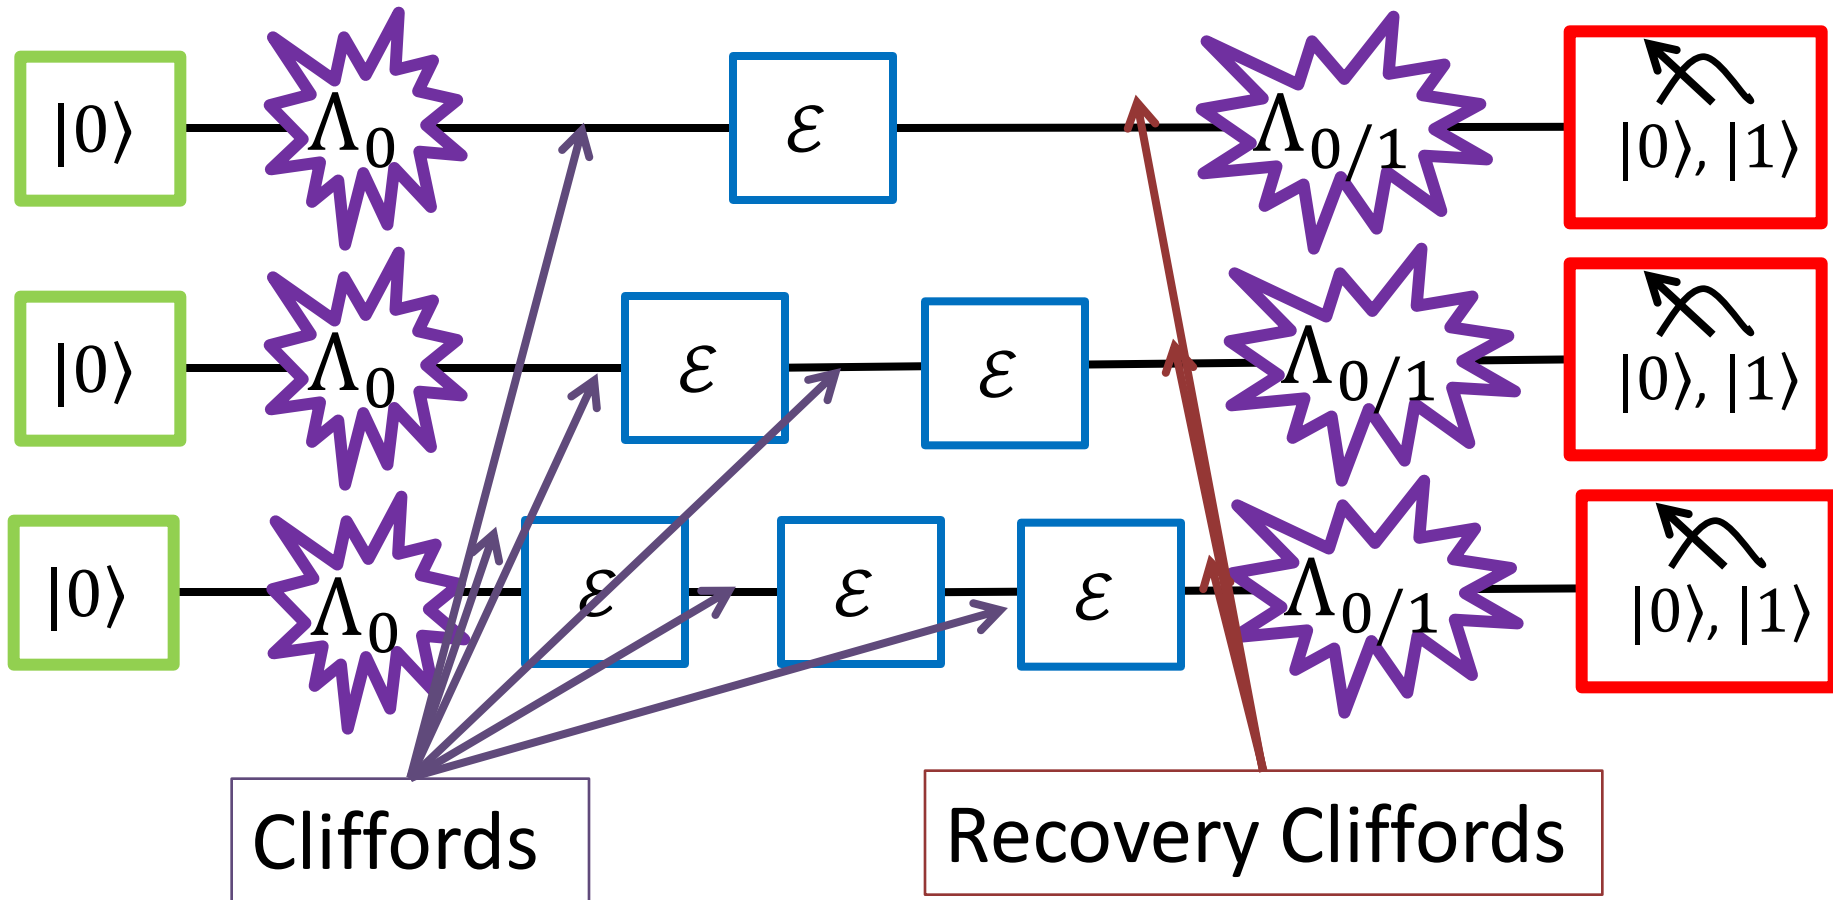

# Negative Witness Test [Moroder et al. '13]

- To be a valid quantum process, must be trace preserving and completely positive
- Complete positivity = in Choi representation, all eigenvalues must be positive
- Negative witness test:
  - Look at value of smallest eigenvalues of reconstructed map in Choi representation.
  - If negative, BAD!

### Negative Witness Test

# Why Negative? (Experimental Setup?)

If state preparation, measurement (or even and Cliffords) are unstable, can cause systematic errors.

# Why Negative? (Data Analysis?)

We fit all 10 exponential decays together to avoid bad fits.  
But we have evidence that this leads to biased results.

# Conclusions and Open Questions

- Can robustly measure unital part of any quantum process
- Experimentally implemented with superconducting qubit system at BBN
- Can we reduce systematic errors in our procedure?
- Can we extract other information efficiently and robustly (compressed sensing)? What about non-unital part?
- How does RB compare to Gate Set Tomography methods?
